Abstract

Background: Hypertension is the most important cardiovascular risk factor in the World Health Organization (WHO) Eastern Mediterranean Region. Excessive salt and sodium intake is directly related to hypertension, and its reduction is a priority of WHO. Bread is the leading staple food in the Region; therefore, reducing the amount of salt added to bread could be an effective measure for reducing salt intake.

Aim: The study sought to determine the levels of sodium and salt in locally produced staple bread from 8 countries in the Region.

Methods: Bread samples were collected randomly from bakeries located in the capital cities of the selected countries. The samples were analysed for sodium content using atomic absorption spectroscopy.

Results: The mean salt content of breads varied from 4.28 g/kg in Jordan to 12.41 g/kg in Tunisia. The mean salt and sodium content in bread for all countries was 7.63 (SD 3.12) and 3.0 (SD 1.23) g/kg, respectively. The contribution of bread to daily salt intake varied considerably between countries, ranging from 1.3 g (12.5%) in Jordan to 3.7 g (33.5%) in Tunisia.
Conclusion: Interventions to reduce population salt intake should target reduction of salt in bread in all countries. The amount of salt added to bread should be standardized and relevant legislation developed to guide bakers. Setting an upper limit for salt content in flat bread (pita or Arabic bread) at 0.5% is strongly recommended. However, salt levels at \( \leq 1\% \) would be appropriate for other kind of breads.

Keywords: Salt, sodium, bread, noncommunicable disease, Eastern Mediterranean Region

Received: 10/07/17; accepted: 05/02/18

Introduction

The average salt intake of > 12 g/day per person in the World Health Organization (WHO) Eastern Mediterranean Region is higher than in most other regions in the world (1). In fact, it is more than double the amount recommended by WHO of 85%) being excreted by the kidneys (3). Sodium is essential for maintenance of plasma volume, acid–base balance, transmission of nerve impulses and normal cell function. However, in excess it causes body fluid imbalance and presents a challenge for excretion by the kidneys, which potentially affects blood pressure and increases the risk of noncommunicable diseases (NCDs) (4). There is a significant positive correlation between high dietary sodium intake and increase in blood pressure in adults and children, and clinical trials have demonstrated that lowering sodium intake reduces blood pressure among individuals with normal as well as high blood pressure (5). High blood pressure is a predisposing factor for cardiovascular diseases and a number of other noncommunicable diseases (NCDs) (6). NCDs are the leading cause of death in the Region; 2.2 million lives are lost to NCDs annually, of which 51% are premature and occur among people aged
There is evidence that salt reduction is a high-impact, preventive intervention that can considerably reduce the burden of NCD-related morbidity and mortality (6). A reduction in dietary intake of sodium of 50 mmol/day could reduce the number of people needing antihypertensive therapy by 50%, the number of deaths from strokes by 22% and the number of deaths from coronary heart disease by 16% (8). Studies conducted in the United States of America (USA) indicated that a 3 g reduction in daily salt intake was associated with a significant decrease in the annual incidence of coronary heart disease, stroke, myocardial infarction, and all-cause mortality, which resulted in an estimated decrease in annual healthcare costs of US$10–24 billion (9). Other studies have shown that decreasing sodium intake to

Entrenched within an overall dietary pattern, sodium intake may come from salt added to cooking or at the table, which is under an individual’s control, but also comes from salt in processed or prepared foods (14). In some countries the major source of dietary sodium is salt added during food preparation, whereas in other countries, processed food products contribute most of the salt in the diet. In the United Kingdom of Great Britain and Northern Ireland (UK) and USA processed foods contribute > 70% of the dietary salt intake, whereas in China, 76% of total salt intake is discretionary (15). Similarly, sources of dietary salt in the Eastern Mediterranean Region vary between low-, middle- and high-income countries due to varying dietary patterns (2). The nutrition transition in the Region has resulted in diets dominated by processed products such as bread, crackers, processed meats, cheese and snack foods and these contribute considerably to the high salt consumption in the Region (1). Observational studies have indicated that bread is the leading staple food in the Region; therefore, reducing the amount of salt added to bread could be an effective measure for the prevention and control of NCDs.

There is a lack of information on the salt content of bread in the Region. Therefore, we conducted an indicative study to measure the salt content in bread from different countries in the Region, so that policy-makers can decide on the appropriate action to achieve salt reduction and whether bread is a priority for such action in the Member States.

**Methods**

**Sample size**

The initial plan was to collect 10 samples of staple bread. This is defined as bread that is eaten routinely and in such quantities that it constitutes a dominant portion of the standard diet for a given population, supplying a large fraction of energy needs. We sent a message to all WHO and Ministry of Health focal points in each Member State. One hundred and five bread samples were collected randomly during 1 November to 15 December 2013, which responded to the study, namely Bahrain, Egypt, Jordan, Kuwait, Qatar, Oman, Lebanon and Tunisia. Bread samples were collected from different bakeries in the capital city of each country; one sample from each bakery. Bread samples were packed in airtight plastic bags, stored under cool, dry conditions and transported to the Royal Scientific Society, Jordan by courier for analysis. Each sample weighed ≥ 150 g. The original samples were all flat bread, which is the most popular
form in the Middle East, which is also called Khubz Arabi and is now widely known as pita bread. This applied to all countries involved in the study, except Tunisia, where round, thick French-type bread was dominant.

**Sample preparation**

The bread samples were ground to form a homogeneous composition, packed and stored in airtight plastic bags at 15°C until use. The samples were analysed for sodium content and the results were used to estimate the population sodium intake resulting from bread consumption in the selected countries.

**Determination of sodium and moisture content**

The sodium and moisture contents of bread were determined using Association of Official Analytical Chemists (AOAC) methods. Moisture content was determined by drying samples in an oven at 105°C to eliminate all moisture in the sample. Analysis of sodium was carried out with the atomic absorption technique after digestion of samples with nitric acid. For this purpose, 5–10 g bread samples were weighed accurately and transferred to the digestion flask and 25 ml nitric acid was added. The digestion flasks were placed on a sand bath at 200°C for 1 hour until the whole organic matter was completely digested. The digested material was transferred to a 100-ml volumetric flask and the volume made up to the mark with deionized water. The samples were analysed for sodium content using atomic absorption and calculated on a dry weight basis. Standard solutions for sodium were prepared and the wavelength readings used to construct a calibration curve. Sodium was read off at 589 nm and sodium content calculated as described below.

Standard deviations for the mean values between the countries were calculated.

**Results**

The mean levels of salt and sodium in bread samples collected from the 8 countries were 7.63 (standard deviation 3.12) g/kg and 3.0 (1.23) g/kg, respectively (Table 1). The highest salt
content was found in Tunisia and Kuwait and the lowest in Egypt and Jordan. The standard deviation shows that there was considerable variation of salt content among the countries. The contribution of bread to daily salt intakes varied considerably among the countries, ranging from 1.3 g (12.5%) in Jordan to 3.7 g (33.5%) in Tunisia, based on a 300 g daily bread intake in most countries of the Region.

**Discussion**

WHO recommends salt reduction in food as one of the cost-effective interventions to control and prevent NCDs. The present study revealed that levels of salt varied within the same type of bread. For example, the level was high in Kuwait 10.97 g/kg (1.1%), while Jordan produced the same flat bread at a level of 4.28 g/kg (0.43%), which means that Kuwait could reduce the salt content in bread without any concern related to the palatability or physical properties of the bread. This also applies to Bahrain and Oman. The highest level of salt was found in the French-type rounded thick bread produced in Tunisia 12.41 g/kg (1.24%), which contributed to 3.2 g of salt intake daily. This represents 64% of the recommended salt intake level set by WHO.

Although the level of salt in flat bread produced in the Eastern Mediterranean Region is not as high as in European bread (1.5–3%) (16), it still represents a major source of salt intake considering that bread is a staple food in the Region and consumed in high quantities by most of the population. Therefore, salt reduction in bread could contribute to reduction of salt intake in the Region. The WHO Regional Office for the Eastern Mediterranean set a target for 30% reduction in salt content as a strategic intervention in the next 3 years.

Technical limitations are rarely a reason to drop bread from a salt reduction programme. Within almost every food category, there is already a broad range of salt levels across similar products that demonstrate the technical feasibility of producing lower salt options. For example, rapid assessment shows that flat bread can be produced with salt levels as low as 0.4% on wet basis, as in Jordan and Egypt. Setting a target for salt content in bread of up to 0.5% (5.0 g/kg bread) is technically possible.

Encouraging the food industry to reformulate its products can be challenging. Several arguments may be used by the industry to justify the difficulty of reducing salt content in some foods, including bread. However, experience from around the world has shown that it is technically possible to reduce the amount of salt significantly without affecting the product. In the UK, for example, the salt content of processed foods sold in supermarkets was initially reduced by 20-30% over 3 years without affecting consumer preference or sales (17). In the UK it was estimated that, for a total campaign cost of £15 million to reduce daily salt intake, £1.5 billion per year would be saved in health care (1). The present study showed that average salt content in Tunisia and Kuwait is > 1% in bread, which accounts for 33.5 and 33.9% of total salt
intake, respectively (Table 1). Similar findings have been reported in the Islamic Republic of Iran and Morocco. Bread is thus a point of focus for salt reduction, with several bakeries already taking action, for example, in the Islamic Republic of Iran, Jordan, Oman, United Arab Emirates (UAE), Morocco, Bahrain, Kuwait and Qatar (1,18,19).

Many Member States in the Region are currently taking active steps based on the policy guidance and recommended actions for salt reduction. Kuwait is gradually reducing the salt content of bread through its public bread supplier, which is the main supplier of bread in the market. In 2013, salt content of bread decreased by 20%. This is an important public health achievement. Qatar has reduced the salt content in bread produced by its main public bread supplier (which has a one third market share) by 20% since early 2014. This percentage reduction has already been achieved in the main bakeries. The Ministry of Health is monitoring the implementation to ensure that the salt level is maintained below the target percentage. A 10% reduction in salt content of the same bread was planned for the end of 2017.

The Islamic Republic of Iran has adopted legislation on salt reduction in a number of products, including establishing maximum levels of salt in all types of bread (1.8%). This level is still high and the recommendation is to set the benchmark at 1% to ensure effective salt reduction intake strategies.

Other Member States have prepared legislation on salt reduction (e.g., Jordan, Bahrain and Oman) or have revised existing legislation to develop benchmarks for salt content in bread. In Morocco an awareness campaign for 300 bakeries was carried out in the region of Grand Casablanca in 2014, resulting in 70% of the bakers committing to reduce added salt in bread. Oman and the UAE also reviewed their food standards and set the benchmark for salt content in bread at 0.5%.

The present study had some limitations in terms of countries covered, representative samples for different types of bread and geographical coverage in each country. However, it was an indicative study conducted in response to the urgent need for information about the salt content in bread, which is lacking in the Region. Considering the time frame and logistic complications, the samples sizes were limited due to the countries’ response and coverage. This study has created more demand by public health policy-makers at regional and national levels to conduct more comprehensive research.

**Recommendations**
In light of these findings, we make the following recommendations.

1. Although the levels of salt in the regional flat bread is not as high as in European bread (2–3 g/kg) (16); the total salt intake is high in the Region due to the high consumption of bread as a staple food.

2. The amount of salt added to bread and other processed food products should be standardized and relevant legislation developed to guide bakers. Setting an upper limit for salt content in flat bread at 0.5% (5g/kg) is strongly recommended for Jordan, Egypt, Lebanon, Sudan, Pakistan, Afghanistan, Oman, UAE, Qatar, Saudi Arabia and occupied Palestinian territory. However, salt levels at 1% (10 g/kg) or less would be good for countries with high levels of salt content in bread such as the Islamic Republic of Iran, Kuwait, Tunisia and Morocco.

3. A monitoring framework on salt usage in confectionary should be established to track compliance to set standards. Salt reduction, especially among manufacturers, should be mandatory and laws and guidelines should be drawn up to guide the process.

4. Country-wide campaigns to raise awareness of salt usage and its potential health impact should be conducted to enable the public to make informed decisions and to encourage manufacturers to lower salt intake in food products.

5. Similar studies on other food products should be carried out to identify major contributors to total salt intake in national diets.

6. Legislation on mandatory food labelling should be introduced or strengthened to facilitate the attainment of salt reduction targets and help consumers make informed decisions about salt levels in food.

**Funding:** This study was funded by WHO.

Évaluation de la concentration de sel dans le pain couramment consommé dans la Région de la Méditerranée orientale

Résumé

Contexte: L'hypertension est le facteur de risque de maladies cardio-vasculaires le plus important dans la Région OMS de la Méditerranée orientale. Une consommation excessive de sel et de sodium est directement liée à l'hypertension, et sa réduction constitue une priorité pour l'OMS. Le pain est le principal produit de première nécessité dans la Région; diminuer la quantité de sel ajouté à ce produit pourrait donc constituer une mesure efficace pour réduire l'apport en sel.

Objectif: La présente étude avait pour objectif de déterminer la teneur en sodium et en sel du pain de base produit localement dans huit pays de la Région.

Méthodes: Des échantillons de pain ont été collectés de façon aléatoire dans des boulangeries des capitales des pays sélectionnés. La teneur en sodium de ces échantillons a été analysée à l'aide de la technique de spectrométrie d'absorption atomique.

Résultats: La teneur moyenne en sel du pain variait de 4,28 g/kg en Jordanie à 12,41 g/kg en Tunisie. La teneur moyenne en sel et en sodium du pain pour l'ensemble des pays était de 7,63 g/kg (écart-type de 3,12) et 3,0 g/kg (écart-type de 1,23) respectivement. La contribution du pain à l'apport en sel quotidien variait considérablement selon les pays, allant de 1,3 g (12,5%) en Jordanie, à 3,7 g (33,5%) en Tunisie.

Conclusion: Les interventions visant à diminuer la consommation de sel des individus devraient avoir pour objectif la réduction du sel ajouté au pain dans tous les pays. La quantité de sel ajouté au pain devrait être standardisée et une législation adéquate devrait être mise au point pour guider les boulangers. Il est vivement recommandé de fixer une limite supérieure pour la teneur en sel du pain plat (pita ou pain arabe) à 0,5 %. Toutefois, des teneurs en sel du pain inférieures ou égales à 1 % conviendraient pour les autres types de pain.
WHO EMRO | Assessment of salt concentration in bread commonly consumed in the Eastern Mediterranean Region

### Summary

The current study aimed to assess the sodium content in breads commonly consumed in the region, highlighting the high levels of salt intake in breads and the associated health risks. The study was carried out by collecting bread samples from selected markets in the region and analyzing them for sodium content. The results showed a significant variation in sodium content across the region's countries, with some countries having sodium content as high as 12.41 g/100g in Jordan and 4.28 g/100g in Tunisia. The average sodium content in breads across the region was found to be between 1.23 and 3.12 g/100g.
