The WHO assists Member States in reducing dissemination of health care associated infections. Photo credit: WHO

Health care-associated infections (HAIs) are considered the most frequent adverse events that threaten patient safety around the world. Around 5% to 15% of patients admitted to acute care hospitals in developed countries acquire HAIs at any given time. The risk of acquiring infection is 2 to 20 times higher in developing countries.

**HAI situation in the Region**

The WHO Eastern Mediterranean Region has one of the highest frequencies of HAIs in the world. The prevalence of HAIs in several countries in the Region is reported to vary from 12% to 18%. The burden of transmissible infections among health-care workers due to unsafe health-care practices is also considerably high in the Region.

Although a substantial proportion of infections and deaths attributable to HAIs can be prevented and low cost interventions for infection prevention and control are available, progress in this field remains slow. This is due to several factors including:

- poor compliance of health-care workers with standard infection control practices
- risky behavioural practices of patients and visitors in health-care settings
poor understanding and implementation of infection prevention and control programmes in health care

lack of programme coherence, when it exists, with other public health services and interventions.

Objectives

The objective of the HAI prevention and control programme area is to establish and strengthen a comprehensive national infection prevention and control approach in the Region through the provision of appropriate resources.

Activities

The current activities of the programme include assessment of national infection prevention and control programmes in the Region in order to guide and advise countries in building their infection prevention and control policies and programmes in accordance with evidence-based practices.

Other key activities include:

- building human resources capacity for infection prevention and control in health care
- developing appropriate policies and strategies for personal protection measures of all health-care providers, including policies on immunization, as appropriate
- standardizing surveillance methods and techniques for generating reliable estimates of burden of HAIs and antimicrobial resistance
- developing recommendations on best infection prevention and control practices associated with health care for patients at high risk of nosocomial infection.
